ABSTRACT

We study general properties of the classical solutions in non-polynomial closed string field theory and their relationship with two dimensional conformal field theories. In particular we discuss how different conformal field theories which are related by marginal or nearly marginal deformations can be regarded as different classical solutions of some underlying string field theory. We also discuss construction of a classical solution labelled by infinite number of parameters in string field theory in two dimensions. For a specific set of values of the parameters the solution can be identified to the black hole solution.

★ Invited talk given at the ‘Strings and Symmetries, 1991’ conference, held at Stony Brook, May 25-30, 1991

In this talk I shall discuss the relationship between the classical solutions of the equations of motion in string field theory and two dimensional conformally invariant field theories. Let us begin by giving a brief motivation for this study. Let us consider two different conformal field theories, each with central charge 26. Thus both of them form consistent background for the formulation of bosonic string theory. A question which naturally arises at this stage is, can these two different conformal field theories be considered as two different classical solutions of some underlying string field theory? The same question may be put in another way. Let us consider formulating string field theory around the background of one of the conformal field theories, so that the S-matrix elements calculated from this string field theory agree with those calculated from the first quantized Polyakov prescription. The question then would be: can we now identify a specific classical solution of this string field theory which will represent string theory formulated around the second conformal field theory? In this talk I shall address the question in this second form.

Yet another way of asking the question is as follows. Let S denote the string field theory action formulated in the background of the first conformal field theory and S' the string field theory action formulated around the background of the second conformal field theory. One then asks: is there a field redefinition which will produce the action of the second conformal field theory starting from the first one? In this formulation the question may also be regarded as the question of background independence of string field theory, since an answer to the above question in the affirmative will guarantee that the string field theory is intrinsically independent of the background in which it is formulated.

The plan of the talk will be as follows. First I shall show that any classical solution of the string field theory corresponds, in some sense, to a generalized conformal field theory. (The precise sense in which it happens will be discussed later.) Next I shall show how, given a marginal deformation of the original conformal field theory around which string field theory is formulated, one can construct a solution of the string field theory equations of motion representing the new con-

formal field theory obtained by this marginal deformation. I shall also show how, using the techniques of string field theory, one can construct an infinite parameter solution in the string theory describing $c = 1$ conformal field theory coupled to gravity. Finally I shall consider a case where the original conformal field theory has a nearly marginal deformation which gives rise to a new conformal field theory. I shall again show how to construct a solution of the string field theory equations of motion that will represent this new conformal field theory. (As we shall see, the situation here is somewhat more subtle since the new conformal field theory does not have the same central charge as the original conformal field theory. Hence we need to combine this with a second conformal field theory which will compensate for the change in the central charge.)

Let us start with a brief review of the formulation of non-polynomial closed string field theory [1] [2] in the background of a given conformal field theory. (For related work in non-polynomial closed string field theory, see refs.[3 – 10] .) As is well known, the first quantized string theory is based on a two dimensional action given by,

$$\mathcal{S} = \mathcal{S}_{matter} + \mathcal{S}_{ghost} \quad (1)$$

where $\mathcal{S}_{matter}$ represents a conformal field theory of central charge 26, and $\mathcal{S}_{ghost}$ represents the action for the ghost fields given by,

$$\mathcal{S}_{ghost} = \int d^2z (b\partial_{\bar{z}}c + \bar{b}\partial_z\bar{c}) \quad (2)$$

Let $\mathcal{H}$ denote the combined hilbert space of the matter and ghost theory. This Hilbert space is characterized by the existence of a unique $SL(2,C)$ vacuum $|0\rangle$ which is annihilated by the Virasoro generators L_n for $n \geq -1$. Here $L_n = L_n^M + L_n^G$, where L_n^M and L_n^G denote the Virasoro generators of the matter and ghost sectors respectively. Using the usual rules of conformal field theory [11], we can then establish a one to one correspondence between the states $|\Phi\rangle$ in $\mathcal{H}$ and

the local operators $\Phi(z, \bar{z})$ in the theory through the relation:

$$|\Phi\rangle = \Phi(0)|0\rangle \quad (3)$$

We shall now define ghost number of various operators in the theory by assigning the fields $b, \bar{b}$ to have ghost number -1 , $c, \bar{c}$ to have ghost number 1 , and all the matter sector fields to have ghost number 0 . This uniquely defines the ghost numbers of all the operators in the theory. We shall further assign the vacuum state $|0\rangle$ to have ghost number 0 . This then defines the ghost number of all the states in the theory: the ghost number of the state $|\Phi\rangle$ given in eq.(3) is the same as that of the operator $\Phi(z, \bar{z})$. Finally we define the BRST charge of the first quantized theory as,

$$Q_B = \sum_{n=-\infty}^{\infty} c_{-n} L_n^M - \frac{1}{2} \sum_{m,n=-\infty}^{\infty} (m-n) : b_{m+n} c_{-m} c_{-n} : \quad (4)$$

where c_n etc. are defined through the relations:

$$c(z) = \sum_n c_n z^{-n+1}, \quad \bar{c}_n = \sum_n \bar{c}_n \bar{z}^{-n+1}, \quad b(z) = \sum_n b_n z^{-n-2}, \quad \bar{b}(\bar{z}) = \sum_n \bar{b}_n \bar{z}^{-n-2} \quad (5)$$

The BRST charge is nilpotent, i.e. $(Q_B)^2 = 0$.

A first quantized string state is an element of the Hilbert space $\mathcal{H}$. More precisely, the physical states of the first quantized theory are the BRST invariant states of $\mathcal{H}$, with the equivalence relation that two states are physically equivalent if they differ by a BRST exact state. Thus the naive guess for the space of second quantized string field (which should correspond to the wave-function or the state of the first quantized string theory) would be the whole Hilbert space $\mathcal{H}$, with BRST invariance being the on-shell condition, and equivalence of physical states differing by a BRST exact state being a consequence of gauge invariance of the string field theory. It turns out, however, that this naive expectation is wrong, at least in the

current formulation of string field theory. First we define a subspace $\mathcal{H}'$ of $\mathcal{H}$ as the space of all states $|\Phi\rangle$ satisfying:

$$c_0^- |\Phi\rangle = 0, \quad L_0^- |\Phi\rangle = 0 \quad (6)$$

where $c_0^- = (c_0 - \bar{c}_0)/\sqrt{2}$, $L_0^- = (L_0 - \bar{L}_0)/\sqrt{2}$. An off-shell string field configuration $|\Psi\rangle$ is then taken to be an arbitrary state in $\mathcal{H}'$ of ghost number 3.^{*}

In order to specify a string field theory, we must write down an expression for the action in terms of the string field $|\Psi\rangle$. This is done in the following way. We first introduce, for all values of $N \geq 3$, a multilinear map (denoted by $\{A_1 \dots A_N\}$) from the N fold tensor product of the Hilbert space $\mathcal{H}$ to the space of complex numbers, and another multilinear map (denoted by $[A_1 \dots A_{N-1}]$) from the $N-1$ fold tensor product of the Hilbert space $\mathcal{H}$ to the Hilbert space $\mathcal{H}$, satisfying the following properties:

$$\begin{aligned} \{A_1 \dots A_N\} &= (-1)^{n_1+1} \langle A_1 | [A_2 \dots A_N] \rangle \\ \{A_1 A_2 \dots (\alpha A_i + \beta B_i) \dots A_N\} &= \alpha \{A_1 \dots A_i \dots A_N\} + \beta \{A_1 \dots B_i \dots A_N\} \\ b_0^- [A_1 \dots A_{N-1}] &= L_0^- [A_1 \dots A_{N-1}] = 0 \\ \{A_1 \dots A_N\} &= (-1)^{(n_i+1)(n_{i+1}+1)} \{A_1 \dots A_{i-1} A_{i+1} A_i A_{i+2} \dots A_N\} \\ Q_B [A_1 \dots A_{N-1}] &= \sum_{i=1}^{N-1} (-1)^{\sum_{j=1}^{i-1} (n_j+1)} [A_1 \dots Q_B A_i \dots A_N] \\ &\quad - \sum_{\substack{\{i_l, j_k\} \\ l \geq 1, k \geq 2}} (-1)^{\sigma\{i_l, j_k\}} [A_{i_1} \dots A_{i_l} c_0^- [A_{j_1} \dots A_{j_k}]] \end{aligned} \quad (7)$$

where $b_0^- = (b_0 - \bar{b}_0)/\sqrt{2}$, n_i denotes the ghost number of the state A_i , and $\sigma(\{i_l, j_k\})$ is a phase factor which is the phase picked up during the rearrangement of the operators $Q_B, b_0^- A_i, \dots, b_0^- A_N$ to $b_0^- A_{i_1}, \dots, b_0^- A_{i_l}, Q_B, b_0^- A_{j_1}, \dots, b_0^- A_{j_k}$.

^{*} Equivalently we could call $b_0^- |\Psi\rangle$ our string field. This has ghost number 2 and is annihilated by b_0^- . Normally what we call first quantized string state is $b_0^- |\Psi\rangle$.

We shall discuss the explicit construction of these multilinear maps later. For the time being let us assume that a set of multilinear maps satisfying eq.(7) exists, and see how this helps us formulate a gauge invariant string field theory. In fact, the action of string field theory takes a simple form when expressed in terms of these maps:

$$S(\Psi) = \frac{1}{2} \langle \Psi | Q_B b_0^- | \Psi \rangle + \sum_{N=3}^{\infty} \frac{g^{N-2}}{N!} \{ \Psi^N \} \quad (8)$$

where $\{ \Psi^N \} = \{ \Psi \Psi \dots \Psi \}$, and Q_B is the BRST charge of the first quantized string theory. This action is invariant under the following gauge transformations:

$$b_0^- \delta | \Psi \rangle = Q_B b_0^- | \Lambda \rangle + \sum_{N=3}^{\infty} \frac{g^{N-2}}{(N-2)!} [\Psi^{N-2} \Lambda] \quad (9)$$

where $| \Lambda \rangle$ is an arbitrary state in $\mathcal{H}'$ with ghost number 2. The proof of invariance of the action (8) under the gauge transformation (9) follows directly from the properties of $[]$ and $\{ \}$ listed in eq.(7) and the nilpotence of the BRST charge Q_B ; we never need the explicit forms of the maps $[]$ and $\{ \}$. Note that the linearized equations of motion $Q_B b_0^- | \Psi \rangle = 0$ implies that physical (on-shell) states correspond to BRST invariant states; – a result that matches with that of the first quantized theory. Furthermore, the linearized gauge transformation law implies that two on-shell states which differ by a BRST exact state are gauge equivalent, again as expected from first quantized theory.

An explicit construction of the maps $\{ \}$ and $[]$ satisfying the properties listed in eq.(7) was constructed in refs.[1][2] and can be expressed in terms of appropriate correlation functions in the combined matter-ghost conformal field theory [2] [12]. We shall not give the general construction here since it will not be needed for our purpose, but shall illustrate the construction by giving the expression for $\{ A_1 A_2 A_3 \}$. This is constructed as follows. Let $\tilde{A}_i$ be the local fields such that,

$$\tilde{A}_i(0) | 0 \rangle = b_0^- | A_i \rangle \quad (10)$$

Then,

$$\{A_1 A_2 A_3\} = -\langle f_1 \circ \tilde{A}_1(0) f_2 \circ \tilde{A}_2(0) f_3 \circ \tilde{A}_3(0) \rangle \quad (11)$$

where f_i ($1 \leq i \leq 3$) are three conformal maps given by,

$$f_1(z) = \left(\frac{1-iz}{1+iz} \right)^{2/3}, \quad f_2(z) = e^{2\pi i/3} f_1(z), \quad f_3(z) = e^{4\pi i/3} f_1(z) \quad (12)$$

and $f_i \circ \tilde{A}_i(z, \bar{z})$ denotes the conformal transform of the field $\tilde{A}_i(z, \bar{z})$ under the map f_i . $\langle \rangle$ denotes the correlation function in the combined matter-ghost conformal field theory. Thus we see that given three states $|A_1\rangle$, $|A_2\rangle$ and $|A_3\rangle$, the quantity $\{A_1 A_2 A_3\}$ is completely defined by eqs.(10)-(12). The first of eq.(7) also determines the state $[A_1 A_2]$ completely once $\{A_1 A_2 A_3\}$ is known for all states A_i .

Similar expressions exist for higher point functions $\{A_1 \dots A_N\}$, such that they satisfy the relations given in eq.(7). Furthermore, when one constructs a string field theory action based on these maps and eq.(8), and computes the S-matrix elements after appropriate gauge fixing, one can recover the usual expression for the S-matrix given by the first quantized Polyakov prescription. In fact the same identities (7) which are responsible for the gauge invariance of the theory also turns out to be crucial in obtaining the correct S-matrix from string field theory.

Let us now investigate some properties of the equations of motion of the theory. The equations of motion obtained by varying the action (8) with respect to the string fields is given by:

$$Q_B b_0^- |\Psi\rangle + \sum_{N=3}^{\infty} \frac{g^{N-2}}{(N-1)!} [(\Psi)^{N-1}] = 0 \quad (13)$$

Let Ψ_{cl} be any classical solution of the equations of motion. The question we shall first ask is: how does string field theory formulated around Ψ_{cl} look like [12]? In particular, we would like to know if it looks like string field theory formulated

around a new conformal field theory. In order to study this question, let us define shifted field:

$$\hat{\Psi} = \Psi - \Psi_{cl} \quad (14)$$

and expand the action in terms of the field $\hat{\Psi}$. It can be easily seen that the action takes the form:

$$S(\Psi) = S(\Psi_{cl}) + \frac{1}{2} \langle \hat{\Psi} | \hat{Q}_B b_0^- | \hat{\Psi} \rangle + \sum_{N=3}^{\infty} \frac{g^{N-2}}{N!} \{\hat{\Psi}^N\}' \equiv S(\Psi_{cl}) + \hat{S}(\hat{\Psi}) \quad (15)$$

where $\hat{Q}_B$ is a new linear operator and $\{ \ }'$ is a new multilinear map, defined as:

$$\hat{Q}_B b_0^- |A\rangle = Q_B b_0^- |A\rangle + \sum_{M=3}^{\infty} \frac{g^{M-2}}{(M-2)!} [(\Psi_{cl})^{M-2} A] \quad (16)$$

$$\{A_1 \dots A_N\}' = \{A_1 \dots A_N\} + \sum_{M=3}^{\infty} \frac{g^{M-2}}{(M-2)!} \{(\Psi_{cl})^{M-2} A_1 \dots A_N\} \quad (17)$$

Let us also define,

$$[A_1 \dots A_{N-1}]' = [A_1 \dots A_{N-1}] + \sum_{M=3}^{\infty} \frac{g^{M-2}}{(M-2)!} [(\Psi_{cl})^{M-2} A_1 \dots A_{N-1}] \quad (18)$$

Note that the shifted action $\hat{S}(\hat{\Psi})$ has the same form as the action (8) with Ψ replaced by $\hat{\Psi}$, Q_B replaced by $\hat{Q}_B$, and $\{ \ }$ replaced by $\{ \ }'$. Furthermore, using the fact that Ψ_{cl} satisfies the equations of motion (13), one can verify [12] the

following relations satisfied by $\hat{Q}_B$, $\{ \}'$ and $[]'$:

$$\begin{aligned}
(\hat{Q}_B)^2 &= 0 \\
\{A_1 \dots A_N\}' &= (-1)^{n_1+1} \langle A_1 | [A_2 \dots A_N]' \rangle \\
\{A_1 A_2 \dots (\alpha A_i + \beta B_i) \dots A_N\}' &= \alpha \{A_1 \dots A_i \dots A_N\}' + \beta \{A_1 \dots B_i \dots A_N\}' \\
b_0^- [A_1 \dots A_{N-1}]' &= L_0^- [A_1 \dots A_{N-1}]' = 0 \\
\{A_1 \dots A_N\}' &= (-1)^{(n_i+1)(n_{i+1}+1)} \{A_1 \dots A_{i-1} A_{i+1} A_i A_{i+2} \dots A_N\}' \\
\hat{Q}_B [A_1 \dots A_{N-1}]' &= \sum_{i=1}^{N-1} (-1)^{\sum_{j=1}^{i-1} (n_j+1)} [A_1 \dots \hat{Q}_B A_i \dots A_N]' \\
&\quad - \sum_{\substack{\{i_l, j_k\} \\ l \geq 1, k \geq 2}} (-1)^{\sigma\{i_l, j_k\}} [A_{i_1} \dots A_{i_l} c_0^- [A_{j_1} \dots A_{j_k}]']'
\end{aligned} \tag{19}$$

The first of these equations tell us that the operator $\hat{Q}_B$ is nilpotent. The rest of the equations are identical to those in eq.(7) with Q_B , $\{ \}$ and $[]$ replaced by $\hat{Q}_B$, $\{ \}'$ and $[]'$ respectively.

Note that the nilpotence of the original BRST charge Q_B as well as the set of relations given in eq.(7) were consequences of conformal invariance of the original system. What we see here is that for every classical solution of string field theory equations of motion we can construct a nilpotent operator $\hat{Q}_B$ and a set of multilinear maps $\{ \}'$, $[]'$ satisfying the same set of properties given in eq.(7). This leads us to believe that every classical solution of string field theory corresponds to a conformal field theory or some generalization of it, characterized by a nilpotent BRST charge $\hat{Q}_B$ and the set of multilinear maps $\{ \}'$ and $[]'$. It remains to be seen whether every classical solution of string field theory indeed corresponds to a conformal field theory. For this one needs to construct the new Virasoro generators $\hat{L}_n$, $\hat{\tilde{L}}_n$ corresponding to the classical solution Ψ_{cl} .

Next let us turn towards construction of explicit solution of equations of motion in string field theory. It is known that given a conformal field theory with a marginal or nearly marginal deformation, we can construct other nearby conformal field theories by perturbing the original conformal field theory by the marginal or

nearly marginal operator. The question we shall address is: given a string field theory constructed in the background of the original conformal field theory, can we construct explicit solutions of the string field theory equations of motion which represent string theory formulated around the perturbed conformal field theory?

Let us start from marginal perturbation. Let $\mathcal{S}_{CFT}$ be the two dimensional action of the original conformal field theory, and $\varphi_i(z, \bar{z})$ be the set of all marginal operators in the theory. The action of the perturbed conformal field theory is then given by,

$$\mathcal{S}'_{CFT} = \mathcal{S}_{CFT} - \lambda_i^{(0)} \int d^2z \varphi_i(z, \bar{z}) + O((\lambda^{(0)})^2) \quad (20)$$

where $\lambda_i^{(0)}$ are small parameters. To order $\lambda^{(0)}$ we can indeed construct a solution of the string field theory equations of motion. This is given by:

$$b_0^- |\Psi_{cl}\rangle = \lambda_i |\varphi_i\rangle_{matter} \otimes c_1 \bar{c}_1 |0\rangle_{ghost} \quad (21)$$

where $\lambda_i \propto \lambda_i^{(0)}$ are also small parameters, and $|\varphi_i\rangle = \varphi_i(0)|0\rangle$. The exact relation between $\lambda_i^{(0)}$ and λ_i will be determined later. Note that (21) is a solution of the linearised equations of motion since $b_0^- |\Psi_{cl}\rangle$ is a BRST invariant state.

The question that we shall now pose is the following [13]? Under what condition can we add systematic corrections to the solution (21) which gives us a solution of the complete string field theory equations of motion to all orders in λ_i ? In order to study this question, let us take a general solution of the form

$$|\Psi_{cl}\rangle = \lambda_i |\varphi_i\rangle_{matter} \otimes c_0^- c_1 \bar{c}_1 |0\rangle_{ghost} + \sum_n \lambda^n |\chi_n\rangle \quad (22)$$

where λ stands for any of the λ_i 's. Let us also define $|\Psi_N\rangle = \sum_{n=1}^N \lambda^n |\chi_n\rangle$. The equation of motion to N th order then takes the form:

$$|E_N\rangle \equiv Q_B b_0^- |\Psi_N\rangle + \sum_{M=3}^{\infty} \frac{g^{M-2}}{(M-1)!} [(\Psi_N)^{M-1}] = O(\lambda^{N+1}) \quad (23)$$

We shall try to prove the existence of a solution of the above equation by induction. In other words we shall assume that eq.(23) holds for a given value of N and then

try to show that under certain conditions it also holds for N replaced by $N + 1$. Since the equation holds for $N = 1$, this would then imply that it holds for all values of N .

The equation $|E_{N+1}\rangle = O(\lambda^{N+2})$ can be rewritten as,

$$\lambda^{N+1} Q_B b_0^- |\chi_{N+1}\rangle = -Q_B b_0^- |\Psi_N\rangle - \sum_{M=3}^{\infty} \frac{g^{M-2}}{(M-1)!} [(\Psi_N)^{M-1}] + O(\lambda^{N+2}) \quad (24)$$

where on the right hand side inside $[]$ we have replaced Ψ_{N+1} by Ψ_N . This is allowed since the difference between $[(\Psi_N)^{M-1}]$ and $[(\Psi_{N+1})^{M-1}]$ can easily be seen to be of order λ^{N+2} for $M \geq 3$. We need to show that it is possible to adjust $|\chi_{N+1}\rangle$ so that eq.(24) is satisfied. The non-triviality in this problem comes from the fact that $Q_B b_0^- |\chi_{N+1}\rangle$ is a pure gauge state; hence unless the state appearing on the right hand side of the equation is also pure gauge, this equation cannot be satisfied by adjusting $|\chi_{N+1}\rangle$. We shall now determine the condition under which the right hand side of eq.(24) is pure gauge.

We rewrite eq.(24) as,

$$\lambda^{N+1} \langle s | Q_B b_0^- |\chi_{N+1}\rangle = - \langle s | Q_B b_0^- |\Psi_N\rangle - \sum_{M=3}^{\infty} \frac{g^{M-2}}{(M-1)!} \langle s | [(\Psi_N)^{M-1}] \rangle + O(\lambda^{N+2})$$

for all $\langle s |$

}

(25)

The set of all states $\langle s |$ (or, equivalently, $\langle s | b_0^-$) may be divided into three classes: pure gauge states for which $\langle s | b_0^- = \langle \Lambda | b_0^- Q_B$ for some $\langle \Lambda |$; physical states which are not pure gauge, but satisfy $\langle s | b_0^- Q_B = 0$; and unphysical states for which $\langle s | b_0^- Q_B \neq 0$. The statement of the preceeding paragraph may now be translated into a different language. If $\langle s | b_0^-$ is either a physical or a pure gauge state, then the inner product of $\langle s |$ with $Q_B b_0^- |\chi_{N+1}\rangle$ vanishes automatically. Thus in order to satisfy eq.(25) for such states $\langle s |$, we must make sure that the right hand side of the equation vanishes identically when the state $\langle s | b_0^-$ is either physical or pure gauge. On the other hand, if the state $\langle s | b_0^-$ is unphysical, then $\langle s |$ has non-vanishing

inner product with $Q_B b_0^- |\chi_{N+1}\rangle$. Hence for such states eq.(25) can be satisfied by adjusting $|\chi_{N+1}\rangle$. (See ref.[13] for a detailed proof of this).

We start with the case where $\langle s|$ is a pure gauge state. In this case eq.(25) takes the form:

$$\sum_{M=3}^{\infty} \frac{g^{M-2}}{(M-1)!} \langle \Lambda | Q_B | [(\Psi_N)^{M-1}] \rangle = O(\lambda^{N+2}) \quad \text{for all } \langle \Lambda | \quad (26)$$

In deriving eq.(26) we have used various properties of $[(\Psi)^{M-1}]$ listed in eq.(7) to express it as $b_0^- c_0^- [(\Psi)^{M-1}]$, and also that $\{Q_B, b_0^-\} c_0^- [(\Psi)^{M-1}] = L_0^- c_0^- [(\Psi)^{M-1}] = 0$. We may evaluate the left hand side of eq.(26) using the properties of $Q_B [(\Psi)^{M-1}]$ given in eq.(7). Using the equation of motion (23) to order λ^N it can be easily seen that the expression given in eq.(26) is of order λ^{N+2} [13]. This, in turn, shows that the condition $\langle s | E_{N+1} \rangle = O(\lambda^{N+2})$ is satisfied automatically if $\langle s|$ is a pure gauge state.

If, on the other hand, we choose the state $\langle s|$ to be a physical state, then the left hand side of eq.(25) still vanishes identically, but there is no reason for the right hand side to vanish. Thus these equations represent genuine obstructions to extending the lowest order solution (21) to higher orders. To understand the significance of these equations, let us study the order λ^2 contribution to these equations. For this we need to substitute the lowest order solution (21) in the right hand side of eq.(25), and take the inner product of this equation with any of the states $\langle s_i | = \langle \varphi_i | c_{-1} \bar{c}_{-1} c_0^-$ for which $\langle s_i | b_0^-$ is physical. This can be easily evaluated and we get the set of equations:

$$\sum_{j,k} C_{ijk} \lambda_j \lambda_k = 0 \quad (27)$$

where C_{ijk} is the coefficient of φ_i in the operator product of φ_j with φ_k . One can now easily recognise the left hand side of the above equation as the β -function of the perturbed conformal field theory. Thus we see that the obstructions represented by taking the inner product of eq.(24) with physical states are string field

theoretic generalization of the β -functions. In order to get a non-trivial solution of the classical equations of motion in string field theory representing a perturbed conformal field theory, one must demand that the β -function of the perturbed theory must vanish.

Before we go on, we shall apply the procedure outline above to construct a set of classical solutions in string field theory representing $c = 1$ conformal field theory coupled to gravity [14]. The corresponding conformal field theory is given by the direct sum of two theories, a free scalar (ϕ_M) field theory with central charge 1, and the Liouville field (ϕ_L) theory which we shall represent by a scalar field theory with a background charge Q at infinity. Q is adjusted so that the central charge $1 + 3Q^2$ of this theory is equal to 25. The field ϕ_L has Euclidean signature, whereas the matter field ϕ_M may have Euclidean or Minkowski signature. We shall refer to ϕ_M as ‘time’ and ϕ_L as space from now on. The region $\phi_L \rightarrow -\infty$ corresponds to weak coupling region, hence we shall refer to it as the asymptotic region.

We shall now try to construct ‘static’, asymptotically flat solutions in this theory. In other words we shall look for solutions which carry zero ϕ_M momentum, and Liouville momentum of the form $-ik_L$ with $k_L > 0$, so that the corresponding background $e^{k_L\phi_L}$ decays as $\phi_L \rightarrow -\infty$. The first step is to classify the physical states with this property. It is well known [15] that in the zero momentum sector, the primary states in the $c = 1$ conformal field theory are labelled by two integers r and s and has dimension (r^2, s^2) . Let us denote these states by $|\varphi_{r,s}\rangle$. It turns out that physical states (of ghost number 2) in the combined matter, Liouville, ghost theory satisfying the conditions of being static and asymptotically flat are of the form [16] $|\varphi_{r,r}\rangle_M \otimes |k_L = (r+1)Q/\sqrt{2}\rangle_L \otimes c_1\bar{c}_1|0\rangle_{ghost}$. Thus to lowest order a solution of the classical equations of motion may be written as,

$$b_0^-|\Psi_{cl}\rangle = \sum_r \lambda_r |\varphi_{r,r}\rangle_M \otimes |k_L = (r+1)Q/\sqrt{2}\rangle_L \otimes c_1\bar{c}_1|0\rangle_{ghost} \quad (28)$$

The question now is whether higher order corrections cause any obstruction to extending these solutions to all orders in λ_r . For this we only need to look for

the inner product of the equations of motion with the physical states. Using the rule of addition of Liouville momentum, and the fusion rules of $c = 1$ conformal field theory, one can show [14] that the inner product of the equation of motion with any physical state vanishes identically in this case. Thus the solution exists to all orders in λ_r . This establishes the existence of a solution in string field theory labelled by infinite number of parameters.

Note that in this case, the expansion of the solution in powers of λ_r may also be regarded as an expansion in powers of $e^{Q\phi_L}$, since each λ_r comes with a specific power of $e^{Q\phi_L}$ in the solution. The expansion is good for large negative ϕ_L , but breaks down for large positive ϕ_L . One may be able to analytically continue the solution past the point where the expansion diverges, or the solution may have a genuine singularity there. With our present technology of string field theory, it is not possible to answer which of these possibilities is correct.

Also note that if we choose $\lambda_1 \neq 0$, but $\lambda_r = 0$ for $r \neq 1$, then the asymptotic expansion of the solution coincides with the recently discovered black hole solution in $c = 1$ string theory [17 – 23]. It can be shown [13] that given the asymptotic expansion, the solution in string field theory is uniquely determined up to gauge transformations. Thus we can say that for these values of the parameters, the solution does represent the black hole solution.

Let us now turn to the case where the original conformal field theory has a nearly marginal operator. Let $\mathcal{S}_{CFT}$ be the action of the original conformal field theory, and $\varphi(z, \bar{z})$ be the nearly marginal operator of dimension $(1 - y, 1 - y)$. It is known that in this case, if the operator product of φ with itself an arbitrary number of times do not produce any other (nearly) marginal operator except φ itself, then the perturbed action:

$$\mathcal{S}' = \mathcal{S}_{CFT} - \lambda^{(0)} \int d^2z \varphi(z, \bar{z}) \quad (29)$$

gives a conformal field theory CFT' for:

$$\lambda^{(0)} = \frac{2y}{C_{\varphi\varphi\varphi}} + O(y^2) \quad (30)$$

where $C_{\varphi\varphi\varphi}$ is the coefficient of φ in the $\varphi\varphi$ operator product expansion. The central charge of the perturbed conformal field theory is given by,

$$c'_{CFT} = c_{CFT} - \frac{8y^3}{(C_{\varphi\varphi\varphi})^2} + O(y^4) \quad (31)$$

From this we see that there is an immediate problem in generalising the previous analysis to this case: if the original conformal field theory describes a consistent background for the formulation of string theory, and hence has central charge 26, then the new conformal field theory does not. Thus we need to be somewhat more careful in formulating the problem. For this let us consider string theory formulated around the background of the original conformal field theory CFT and a free scalar field (X^0) theory with background charge Q , so that the total central charge $1 - 3Q^2 + c_{CFT}$ is equal to 26.[★] This describes a consistent background for the formulation of string field theory. In this case, we can get another consistent background for the formulation of string field theory, by taking the direct sum of the conformal field theory CFT' and the free scalar field theory with background charge Q' , so that the total central charge $1 - 3(Q')^2 + c'_{CFT}$ again becomes equal to 26. We now ask the question: if we construct a string field theory in the background of the first conformal field theory, can we construct a classical solution of this string field theory that represents the second conformal field theory?

Construction of the solution proceeds exactly in the same way as in the previous

★ We have, for definiteness, taken X^0 to be a time-like coordinate, but our analysis goes through without any change even if we choose X^0 to be space-like. Note that if we take X^0 to be space-like, and CFT to be one of the minimal models, the system describes minimal model coupled to gravity, with X^0 identified as the Liouville field.

case. We start with a trial solution of the form:

$$|\Psi_{cl}\rangle = \lambda c_0^- c_1 \bar{c}_1 |\varphi\rangle_{matter} \otimes |0\rangle_{ghost} + \sum_{n=2}^{\infty} \lambda^n |\chi_n\rangle \quad (32)$$

and try to show the existence of the solution of the equations of motion by using the method of induction. In this analysis we treat λ to be of the same order as y since from hindsight we know that this would be the case. As before, the only possible obstruction comes from the inner product of the equations of motion with the physical states. The assumption that the operator product of φ with itself does not contain any other (nearly) marginal operator except itself, implies that the only possible obstruction comes from taking the inner product of the equations of motion with the state $c_0^- c_1 \bar{c}_1 |\varphi\rangle_{matter} \otimes |0\rangle_{ghost}$.[†] To order λ^2 , the equation looks like:

$$2\lambda y - \frac{g}{\sqrt{2}} C_{\varphi\varphi\varphi} \lambda^2 + \text{Polynomials in } \lambda \text{ and } y \text{ of degree } \geq 3 = 0 \quad (33)$$

The above equation has a perturbative solution of the form:

$$\lambda = \frac{\sqrt{2}}{g} \frac{2y}{C_{\varphi\varphi\varphi}} + \sum_{n \geq 2} a_n y^n \quad (34)$$

Comparing with eq.(30) we see that the coefficient of perturbation $\lambda^{(0)}$ in the conformal field theory is related to λ through the relation:

$$\lambda^{(0)} = \frac{g}{\sqrt{2}} \lambda + O(\lambda^2) \quad (35)$$

We can now construct the solution to any arbitrary order in λ following the procedure outlined above (for details see ref.[13]). In particular we can study the

[†] This state is not actually a physical state, since φ does not have dimension (1,1). It turns out, however, that in obtaining the solution in power series in λ , we need to treat this state on the same footing as a physical state, otherwise in the process of obtaining the solution we need to invert a matrix, one of whose eigenvalues is proportional to y . As a result, the inverse of this matrix, acting on an order y^{n+1} term, will give an order y^n term, thus upsetting the counting of powers of y [13].

order λ^3 contribution to the solution, and ask if we can see the change in the background charge from Q to Q' . (Note that $Q^2 - Q'^2$ is given by to $(c_{CFT} - c'_{CFT})/3 = (8y^3/C_{\varphi\varphi\varphi}^2) + O(y^4)$.) For this, we note that the presence of the background charge in the X^0 system is equivalent to giving the dilaton a background value proportional to QX^0 [24]. Thus a change in Q will correspond to a change in the background value of the dilaton field. Examining the solution to order λ^3 we find that such a background is indeed present in the solution. In particular, we can calculate $Q - Q'$ from the solution and find that [13]:

$$Q - Q' = \frac{8y^3}{6Q(C_{\varphi\varphi\varphi})^2} \quad (36)$$

in agreement with eq.(31) to this order. Note that if we did not know the central charge of the perturbed conformal field theory, the above procedure would give us a way to calculate this.

This finishes our discussion of explicit construction of the solutions of string field theory. We can now ask: given these solutions, what evidence do we have that they indeed represent string theory formulated in the background of perturbed conformal field theory? In order to answer this question, we need to compare string field theory action $\hat{S}(\hat{\Psi})$ formulated around these new backgrounds with string field theory action $\tilde{S}(\tilde{\Psi})$ formulated directly in the background of the perturbed conformal field theory. First we can compare the coefficient $\hat{Q}_B$ of the quadratic term in $\hat{S}$ with the BRST charge $\tilde{Q}_B$ of the perturbed conformal field theory. It turns out that to order λ these two charges are related to each other by an inner product preserving similarity transformation [25], provided we identify $\lambda_i^{(0)}$ with $g\lambda_i/\sqrt{2}$ as in eq.(35). Hence the spectrum of $\hat{Q}_B$ and $\tilde{Q}_B$ are identical, and the kinetic term of $\hat{S}$ is identical to the kinetic term of $\tilde{S}$ after a linear field redefinition. The next question is whether the interaction terms of $\hat{S}$ and $\tilde{S}$ can also be shown to be identical. In this case it turns out that to order λ , if we calculate the S-matrix elements from the action $\hat{S}$, they are identical to the S-matrix elements calculated

in string theory in the background of perturbed conformal field theory [26].[★] This, in turn, gives a strong indication that there is, in fact, a field redefinition which takes us from $\hat{S}(\hat{\Psi})$ to $\tilde{S}(\tilde{\Psi})$. Generalization of these results to higher orders in λ has not been carried out. Also, so far, the explicit field redefinition which takes us from $\hat{S}$ to $\tilde{S}$ has not been constructed.

To summarise, we have shown how we can use string field theory to demonstrate that conformal field theories which are related by marginal and nearly marginal operators can be regarded as different classical solutions of the same underlying string field theory. We have also discussed how to construct explicit classical solutions of string field theory representing these perturbed theories. In this process, we have obtained string field theoretic expression for the β -function and the central charge of the perturbed conformal field theory. Finally, for $c = 1$ conformal field theory coupled to gravity, we have explicitly constructed an asymptotically flat, static (possibly singular) solution labelled by infinite number of parameters. For a specific set of values of the parameters the solution reduces to the recently discovered black hole solution.

Acknowledgements: I would like to thank the organisers of the conference for their hospitality during my stay at Stony Brook.

★ This has been shown for S-matrix elements with arbitrary number of tachyonic external legs, and also for S-matrix elements with three arbitrary external legs.
